Abstract. The problem of determining the ability of a liquid to penetrate into the structure of a composite material prepared using reinforcing glass fabrics and a polyester binder is solved. The determination of the ability of water to penetrate into the structure of samples cut from a common plate of polymer composite materials (PCM) is carried out by determining the change in weight of samples before and after their immersion in a container with a liquid medium (water) for a certain period of time. The ability of water penetration into the composition of this material has been established depending on its structure, that is, on the location of the reinforcing material. The mechanical properties (tensile, compressive and bending strength) of a composite material after its removal from a liquid container are presented. The problem of the possibility of the effect of processing the ends of cut test samples with polyester resin on the ability of liquid penetration into the composition of a PCM is solved. For this purpose, samples cut from a common plate were immersed in containers with water, while the ends of one batch of samples were coated with polyester resin, and the other batch was uncoated. The influence of the presence of samples in a liquid medium (water) with a certain ratio of layers of reinforcing material (glass wool and roving fiberglass) on their mechanical characteristics during bending, stretching and compression has been established. The test results of the samples are presented, which showed a direct dependence of the tensile strength and destructive force on the number of roving layers in the PCM structure of the samples whose edges were treated with polyester resin. During the experiments, the ability of liquid penetration into the structure of composite materials and changes in mechanical properties as a result of immersion of these materials in a liquid medium were determined. The obtained results of experimental tests of samples made of PCM with various reinforcement schemes will justify their widespread use in ship hull structures, in particular, as a material for the manufacture of ship tanks.

Keywords: marine tanks, polymer composite materials, water, reinforcing material, binder, penetration, tensile strength, applied load, destructive load

Аннотация. Решается задача определения способности жидкости к проникновению в структуру композиционного материала, подготовленного с применением армирующих стеклянных тканей и полизэфирного связующего элемента. Определение способности воды проникать в структуру образцов, нарезанных из общей плиты полимерного композитного материала (ПКМ), производится путем определения изменения веса образцов до и после их погружения в емкости с жидкостью средой (вода) на определенный промежуток времени. Установлена способность проникновения воды в состав данного материала в зависимости от его структуры, т. е. от расположения армирующего материала. Представлены механические свойства (предел прочности при растяжении, сжатии и изгибе) композиционного материала после его изъятия из емкости с жидкостью. Решается задача о возможности влияния обработки торцов нарезанных образцов для испытаний полизэфирной смолой на способность проникновения жидкости в состав ПКМ. С этой целью образцы, нарезанные из общей плиты, погружались в емкости с водой, при этом торцы одной партии образцов были покрыты полизэфирной смолой, а другая партия оставалась без покрытия. Установлено влияние нахождения образцов в жидкости среде (вода) с определенным соотношением слоев армирующего материала (стекломата и ровинговой стеклоткани) на их механические характеристики при изгибе, растяжении и сжатии. Приведены результаты испытаний образцов, которые показали прямую зависимость предела прочности и разрушающей действующей силы от количества ровинговых слоев в структуру ПКМ у образцов края, которые были обработаны полизэфирной смолой. В ходе выполнения экспериментов определена способность проникновения жидкости в структуру композиционных материалов и изменения механических свойств в результате погружения данных материалов в жидкую среду. Полученные результаты экспериментальных испытаний образцов из ПКМ при различных схемах армирования оправдают их широкое применение в судовых корпусных конструкциях (в частности, как материал для изготовления судовых цистерн).

Ключевые слова: судовые цистерны, полимерные композитные материалы, вода, армирующий материал, связующий элемент, проникающая способность, предел прочности, прилагаемая нагрузка, разрушающая нагрузка

Introduction

The widespread use of products made of polymer composite materials (PCM) in the field of shipbuilding is explained by their high mechanical characteristics compared to products made of steel, in particular, specific strength, as well as the possibility of obtaining finished products without the use of traditional expensive mechanical treatments, etc. [1].

Fiberglass is a composite material consisting mainly of a fiberglass filler and a polymer matrix (binder) that combines the filler into a single homogeneous composition. Fiberglass based on polyester and vinyl ester resins is a structural material capable of with-

standing all types of loads, including shock and vibration. According to its physical characteristics, fiberglass is considered resistant to many aggressive liquids, insoluble and non-melting, has high chemical resistance, low water absorption and an environmentally friendly product. One of the main advantages of composite materials is their minimal conductivity, which provides high protection against fire. Composite materials have high maintainability, low weight, biological resistance, structural rigidity, durability and impact resistance [2].

The purpose of this study is to determine the effect of water on the weight and mechanical properties

of samples made of PCM with treated and untreated edges with polyester resin when they are immersed in a liquid with a sustained period of time. Determination of the influence of the location of reinforcing layers (glass wool and roving fiberglass) on the ability of liquid penetration into the structure of the composite material. The object of the study is six layered samples with treated and untreated edges with polyester resin, made of composite materials using glass fabrics and with a different arrangement of reinforcing materials and a different quantitative ratio of layers.

Methods of manufacturing and testing samples from PCM

For further experiments, plates were made of PCM of two different reinforcement schemes, from which samples were subsequently cut using a milling machine and a sawtooth disk made of hardened steel. The samples from the PCM were made for testing for three-point bending, compression and stretching.

The pattern of reinforcement of the samples is as

follows:

- scheme I: glass wool, glass wool, roving fiberglass, roving fiberglass, glass wool, glass wool;
- scheme II: roving fiberglass, roving fiberglass, glass wool, glass wool, roving fiberglass, roving fiberglass.

The samples from each scheme were divided into two groups:

- the first group, samples without edge treatment with polyester resin;
- the second group, samples with polyester resin edge treatment.

The edges of the samples of the second group are treated with polyester resin Yaropol 110, using a brush with natural bristles. After processing the edges of the samples, they must be left for 48 hours at normal room temperature, only after complete drying, the processed samples are weighed, immersed in water for 90 days at room temperature 23 °C and humidity 50%. Table 1 shows the weight characteristics of samples with different reinforcement schemes [3].

Samples from PCM of different reinforcement schemes are weighed before immersion in water on certified equipment of the laboratory of Ship Mechanical Disciplines of the Caspian Institute of Marine and River Transport named after General-Admiral F. M. Apraksin.

After the expiration of the specified period of time, samples of different reinforcement schemes are removed from the water, wiped dry with a cotton cleaning cloth and weighed (Table 2) on certified laboratory electronic scales of the VLTE-310T series [4].

According to the measurement results of the average mass values of the samples of the two reinforcement schemes without edge treatment before and after

soaking in water, it was found:

- the increase in the masses of the samples intended for tensile tests of the I and II reinforcement schemes is 0.556 and 0.3 grams, respectively;
- the increase in the mass of samples intended for compression tests of the I and II reinforcement schemes is 0.004 and 0.012 grams, respectively;
- the increase in the mass of samples intended for bending tests of the I and II reinforcement schemes is 0.342 and 0.198 grams, respectively.

The results of measuring the average mass values of samples of two reinforcement schemes with edge treatment with polyester resin before and after soaking

in water showed that the average values of changes in the weight parameters of the samples increase, but at the same time:

– for samples prepared for tensile tests, the increase in the average weight values of I and II reinforcement schemes is 1.084 and 0.654 grams, respectively;

– for samples intended for compression tests, this increase is 0.0044 and 0.042 grams;

– for samples intended for bending tests, the increase in the average values of weight characteristics is 0.966 and 0.39 grams.

Based on the conducted studies, it follows (Fig. 1) that, lead has good penetrating abilities, causes swelling, accompanied by an increase in mass, volume,

most noticeable on samples from PCM with treated edges with polyester resin [5].

Fig. 1. Samples from the PCM of two reinforcement schemes with treated edges with polyester resin after soaking in water

Tests of samples from PCM in order to determine their mechanical characteristics after soaking in water were carried out on certified testing machines at the

Department of Ship-Mechanical Disciplines of the Caspian Institute of Marine and River Transport named after General-Admiral F. M. Apraksin.

Testing of samples from PCM for three-point bending

On the basis of regulatory and technical documentation, test samples are produced. Testing of samples from PCM for static bending is carried out in accordance with USS 4648-2014, samples are made of rectangular shape with dimensions of length and width 200×20 mm (Fig. 2, 3) [6].

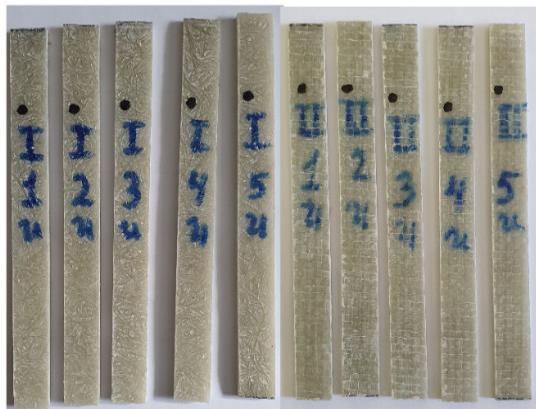

Fig. 2. Samples of two different reinforcement schemes without edge treatment with polyester resin for the three-point bending test

According to the average thickness of the samples according to the formula $L = (16 \pm 1)h$, the distance between the supports is determined. The test samples are placed on supports and subjected to three-point bending at a constant loading rate until complete destruction, while measuring the destructive load applied to the sample [7]. The applied load is fixed at 10 mm/min. The bending strength of the PCM is calculated by the ex-

pression:

$$\sigma = \frac{3F_{\max}L}{2bh^2},$$

where F_{\max} – is the value of the loading force, N; L – is the fixed distance between the installed supports, mm; b – is the size of the sample in width, mm; h – thickness of the sample, mm.

The fixed distance between the installed supports is calculated using the formula

$$L = (16 \pm 1)h.$$

Fig. 3. Samples of two different reinforcement schemes from the edge treatment with polyester resin to the three-point bending test

Table 3 shows the results of testing samples from PCM for three-point bending.

Table 3

Test results of samples from PCM for three-point bending

5	115	224	115	250.5
<i>Average values</i>	<i>104</i>	<i>204.72</i>	<i>109</i>	<i>254.92</i>
Samples with edge treatment with polyester resin				
1	95	175	115	304
2	90	173.7	90	243.6
3	85	159.5	125	260
4	85	164.8	110	250
5	100	200.5	115	261
<i>Average values</i>	<i>91</i>	<i>174.7</i>	<i>111</i>	<i>263.72</i>

The results of the bending tests carried out show that the average value of the loading force on the samples of the first group (without processing the edges with polyester resin, Fig. 4) after soaking in water is greater than that of the second group (the edges

of which are treated with polyester resin), but the average tensile strength of the samples of the second group (the edges of which are treated with polyester resin, Fig. 5) is an order of magnitude higher.

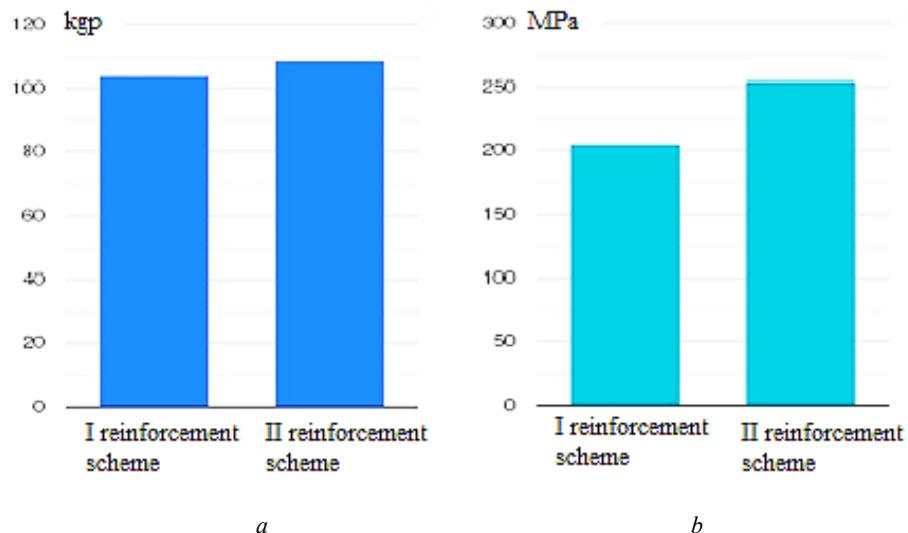

Fig. 4. Graphs of changes in the average values of the destructive forces (a) and strength limits (b) of samples without processing the edges with polyester resin during the bending test

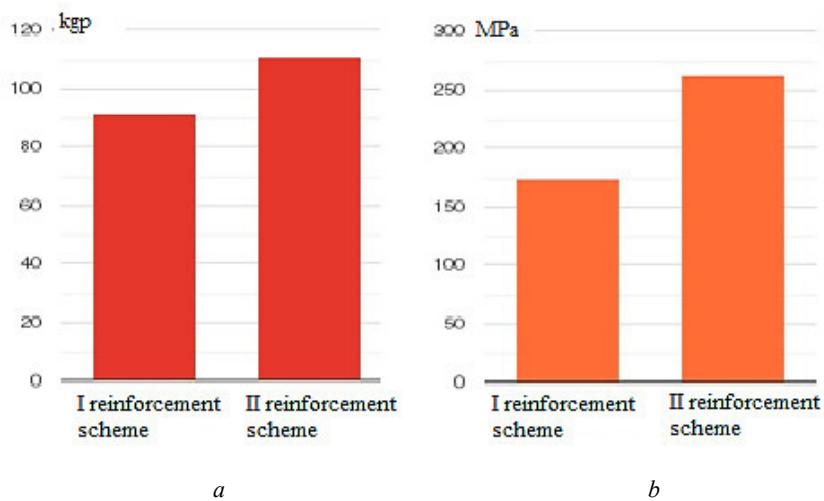

Fig. 5. Graphs of changes in the average values of destructive forces (a) and strength limits (b) of samples with edge treatment with polyester resin during bending testing

Tensile testing of samples from PCM

According to USS 11261-17, in order to determine the value of the tensile strength, the samples must have a flat shape with dimensions of 250 mm in length, 25 mm in width and 2 mm in thickness [8]. The tensile strength at PCM is determined by the formula:

$$\sigma = \frac{F_{\max}}{A}, \quad (1)$$

where $A = bh$ – the cross-sectional area of the sample, mm^2 .

The test samples (Fig. 6, 7) are stretched along their axis at the same speed of 5 mm/min, the tensile load is measured simultaneously and the breaking load and tensile strength are determined. Table 4 shows the results of tensile testing of samples from PCM.

Fig. 6. Samples of two different reinforcement schemes without edge treatment with polyester resin for tensile testing

Fig. 7. Samples of two different reinforcement schemes from the edge treatment with polyester resin to the tensile test

Table 4

The results of tensile testing of samples from PCM

Sample number	Reinforcement scheme			
	I		II	
	F_{max} , kgp	σ , MPa	F_{max} , kgp	σ , MPa
Samples without edge treatment with polyester resin				
1	2 100	147.6	2 700	227.7
2	2 500	164.4	2 100	188.6
3	2 350	172	2 400	205
4	1 900	133.7	2 350	222.5
5	2 600	169.8	2 250	198.8
<i>Average values</i>	2 290	198.444	2 360	208.52
Samples with edge treatment with polyester resin				
1	2 700	184.7	2 650	181
2	2 250	152	2 300	203
3	2 200	144	2 100	177.5
4	2 100	130	2 250	192.6
5	2 250	138.7	2 500	227
<i>Average values</i>	2 300	149.88	2 360	196.22

A comparative analysis of the results of the PCM tensile tests shows that the average applied load of the samples of the second group (the edges of which are treated with polyester resin, Fig. 8) after soaking in water is slightly greater or equal to the samples of the first group (without processing the edges with polyester resin, Fig. 9), and the average tensile strength of the samples of the first group (without processing the edges with polyester resin) is an order of magnitude higher.

Compression testing of samples from PCM

According to the requirements of USS 4651-2014,

samples intended for compression tests (Fig. 10, 11) are made in a parallelepiped shape with dimensions $l \times b \times h$ corresponding to $10 \times 10 \times 4$ mm [9].

The loading and compressive force is directed at the samples along the axes, perpendicular to the direction of the reinforcing layers and at a uniform rate until destruction or until the load decreases. It should be noted that the value of the compressive load on the samples is recorded during the entire course of the test. Table 5 shows the results of compression testing of samples from PCM.

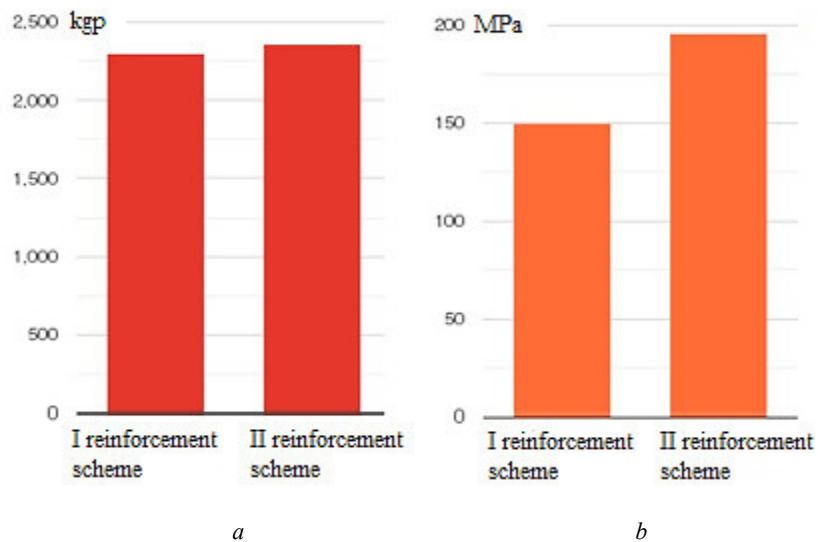

Fig. 8. Graphs of the dependence of the average values of destructive loads (a) and tensile strengths (b) during tensile testing of samples with edge treatment with polyester resin

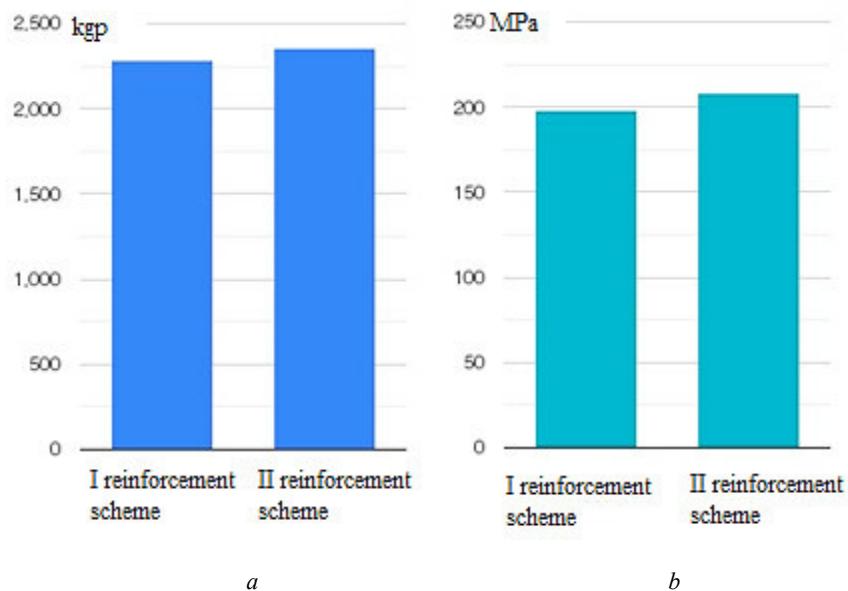

Fig. 9. Graphs of the dependence of the average values of destructive loads (a) and tensile strengths (b) during tensile testing of samples without edge treatment with polyester resin

1	2 700	482.4	2 750	552.7
2	2 300	437.6	2 350	473
3	2 300	429	2 750	562
4	2 600	476.6	2 800	568
5	2 900	513.2	2 850	578
Average values	2 560	467.76	2 700	546.74

Samples from the PCM are installed in the center of the support pads of the R-5 testing machine. The uniform speed of the applied load is fixed at a value of 1 mm/min.

The values of the compressive strength of the samples are calculated according to the formula (1).

A comparative analysis of the results of PCM tests

for destructive compression load showed that the average values of the applied load and the tensile strength of the samples of the second group (whose edges are treated with polyester resin, Fig. 12) are higher than those of the samples of the first group (whose edges are not treated with polyester resin, Fig. 13).

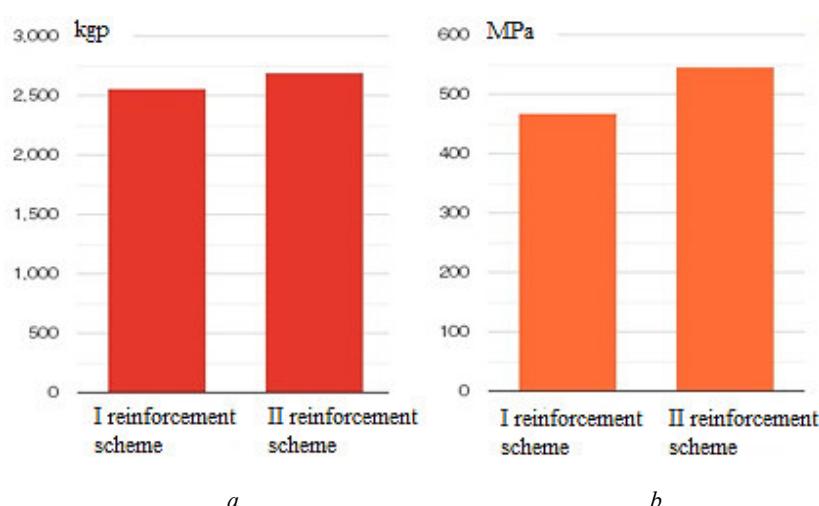

Fig. 12. Graphs of the dependence of the average values of destructive loads (a) and tensile strengths (b) during compression testing of samples with edge treatment with polyester resin

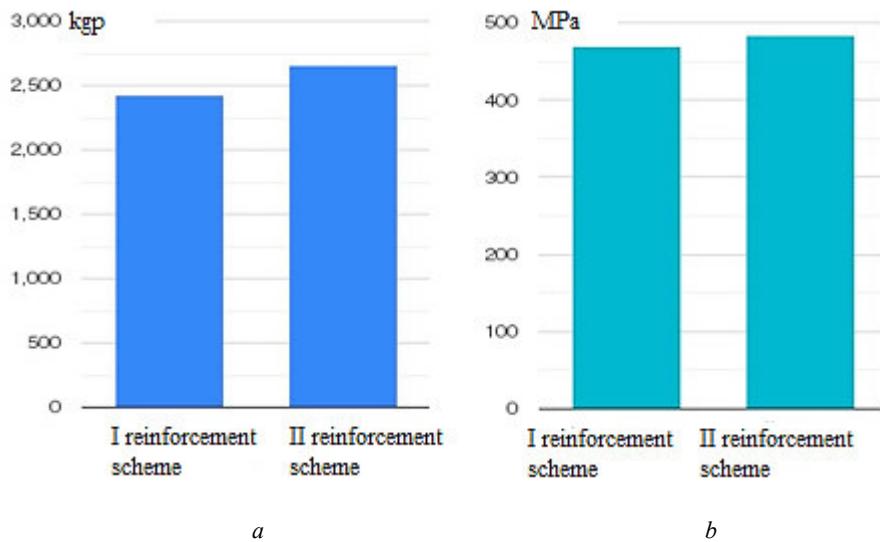

Fig. 13. Graphs of the dependence of the average values of destructive loads (a) and tensile strengths (b) during compression testing of samples without edge treatment with polyester resin

Conclusion

Based on the results obtained, it can be concluded that the ability of liquid penetration (in this case, water) into the structure of the PCM is influenced by the structure and location of the layers of the composite material, as well as its dimensions. The liquid has a better penetrating ability, especially for samples with small dimensions when the glass wool layer is located

outside (scheme I), regardless of whether or not the edges are treated with resin.

The penetration of liquid into the structure of PCM negatively affects their mechanical characteristics by reducing the values of tensile, compressive and bending strengths, while this decrease is less noticeable when the layers of roving fiberglass are located outside.

Information about the authors / Информация об авторах

Maksim A. Meleshin – Postgraduate Student of the Department of Design and Technology of Ship Construction; Volga State University of Water Transport; meleshin.maxim@yandex.ru

Ali Salamekh – Candidate of Technical Sciences; Professor of the Department of Ship Mechanical Disciplines; Caspian Institute of Sea and River Transport after General-Admiral F. M. Apraksin, branch of Volga State University of Water Transport; a.salameh@mail.ru

Victor A. Mamontov – Doctor of Technical Sciences, Assistant Professor; Professor of the Department of Shipbuilding and Energy Complexes of Marine Engineering; Astrakhan State Technical University; mogoy@mail.ru

Vladimir P. Bulgakov – Doctor of Technical Sciences, Professor; Professor of the Department of Shipbuilding and Energy Complexes of Marine Engineering; Astrakhan State Technical University; secmt@astu.org

Konstantin N. Sakhno – Doctor of Technical Sciences, Professor; Head of the Department of Shipbuilding and Energy Complexes of Marine Engineering; Astrakhan State Technical University; mogoy@mail.ru

Максим Алексеевич Мелешин – аспирант кафедры проектирования и технологии постройки судов; Волжский государственный университет водного транспорта; meleshin.maxim@yandex.ru

Али Саламех – кандидат технических наук; профессор кафедры судомеханических дисциплин; Каспийский институт морского и речного транспорта имени генерал-адмирала Федора Матвеевича Апраксина, филиал Волжского государственного университета водного транспорта; a.salameh@mail.ru

Виктор Андреевич Мамонтов – доктор технических наук, доцент; профессор кафедры судостроения и энергетических комплексов морской техники; Астраханский государственный технический университет; mogoy@mail.ru

Владимир Павлович Булгаков – доктор технических наук, профессор; профессор кафедры судостроения и энергетических комплексов морской техники; Астраханский государственный технический университет; secmt@astu.org

Константин Николаевич Сахно – доктор технических наук, профессор; заведующий кафедрой судостроения и энергетических комплексов морской техники; Астраханский государственный технический университет; mogoy@mail.ru
